(54) **Printhead servicing station for printers.**

(57) Methodology and apparatus are described which employ an improved modular service station (16) design wherein a printhead-servicing sled (20) is selectively vertically driven to effect execution of servicing tasks. In keeping with its desired modularity, the sled (20) is made readily removable using an improved clamp and sled (20) arrangement. The sled (20) is driven by a unique drive system (30) such drive system (30) being capable of effectively selectively stalling or locking instrumentality such as the sled (20) in various positions defined along its path of vertical movement. To save time and space, both the printhead (14a, 14b) and the servicing mechanism such as the wipers (24a, 24b) and the caps (22a, 22b) are moved so as to place them in proper relative positions for execution of a task. Precise relative positions of the servicing mechanism and the printhead (14a, 14b) are achieved and maintained during the course of a servicing task such as printhead capping by employment of an improved printhead registration system (30) which limits relative rotation between the printhead (14a, 14b) and the servicing mechanism.

Technical Field

The present invention relates generally to method and apparatus which provide low-cost solutions to problems related to the alignment, replacement and transport of instrumentality. Such methodology and apparatus has proven particularly useful in applications related to the servicing of a printhead in a printer and is generally described as such herein.

Background Art

In a conventional printer, printhead servicing is accomplished by moving the printer's printhead to a predetermined servicing position, sliding the servicing mechanism to a predetermined point of interface, and performing the desired servicing task. The servicing mechanism generally forms a part of a service station, the service station being housed in the printer's chassis so as to shield the station from inadvertent harm. In order to bring the servicing mechanism into interface with the printhead, it is conventional to act on the station using a carriage which moves the printhead into its servicing position. Such carriage generally acts on the station by cammed engagement therewith moving the servicing mechanism into the desired interface position. By virtue of the carriage's engagement with the service station, the servicing mechanism is selectively locked or held in place during operation of the serving task. After the servicing task is performed, the printhead carriage disengages the station and the servicing mechanism is allowed to fall back into its initial position.

Although relatively simple, and thus inexpensive, the just-described arrangement has been characterized by less than accurate alignment between the servicing mechanism and the to-be-serviced printhead. Such inaccuracies are due in large part to the method of service station transport, but are also related to the manner in which the servicing mechanism is locked or held in place during operation of the servicing task. Known arrangements, for example, have failed to provide for adequate registration of the service station, generally allowing movement in all but one of the six degrees of linear and rotational freedom. This movement, in turn, has led to ineffective capping of printheads, a servicing task which is commonly performed in ink-jet printers, printers in which wet-ink printheads (pens) are employed.

Another area in which known servicing arrangements have left room for improvement is in the area of service station adaptability and replaceability; features which accommodate use of a single printer chassis and/or service station in different printer applications. It may, for example, be desirable to provide a chassis or service station which accommodates service of various printhead configurations (e.g. for single- or plural-printhead applications). Such adapt-

ability would likely lead to lower manufacturing and design costs, and thus to a lower end-user purchase price. Despite the foreseeable benefits, known printers do not adequately provide for the adaptation or replacement of printhead service stations. Prior art printers have instead employed service stations which are manufactured as an integral part of the printer's chassis, and are thus not suitable for easy substitution where an alternative printer application is desired.

Disclosure of the Invention

The invented method and apparatus address the above-identified problems by providing a service station of improved modular design. The improved service station is made easily removable from a printer by containing the service station in a framework which forms a part thereof. The framework, which is selectively secured to the printer's chassis, is removable in a manner which accommodates removal of the service station as a whole.

The service station, in keeping with its desired modularity, includes a removable sled which selectively is driven vertically into a servicing elevation to effect servicing of the printer's printhead. Servicing is effected using servicing mechanism such as a printhead wiper or a printhead cap, either of which is mounted on the sled so that it may be selectively changed along with the sled. The sled is driven by a unique drive system which, in the preferred embodiment, forms a part of the improved service station. The drive system is capable of effectively locking instrumentality such as the sled and the servicing mechanism in positions predefined relative to reference structure such as the printer's chassis.

The drive system is made up generally of a instrumentality-carrying rack, a rotating pinion, and a worm gear, such components being configured in an arrangement so as to effect locking of the instrumentality upon corresponding lock-up of the worm gear. The rack, which is coupled to the pinion gear, is selectively moved relative to the reference structure in a first direction along a predetermined path, such movement being limited selectively by a movable stop. Limiting action is effected by selected placement of the stop in a first position wherein the stop is engaged upon movement of the rack so as to build up torque in the driving pinion gear. The stop, however, is controllably movable to a position wherein the pinion gear torque is alleviated, allowing the rack, and thus the instrumentality carried thereby, to continue in the first direction along the predetermined path.

Because of the various adaptations which are possible in the presently improved modular service station design, it is generally necessary, before a printhead is serviced, to identify the desired servicing task. Once this is done, it is further necessary to de-

2

3

EP 0 590 850 A2

4

termine what relative positions of the printhead and the sled are necessary in order to accomplish the task. The printhead is then moved to the proper servicing position and the task is executed.

It is, on occasion, important to ensure that precise relative positions of the servicing mechanism and the printhead are achieved and maintained during the course of a servicing task such as printhead capping. For this reason, the improved service station which is herein disclosed utilizes a registration system which limits relative rotation between the printhead and the servicing mechanism about an axis which corresponds to the direction of relative approach. This is accomplished by providing the printhead carriage with a plurality of spaced detents and providing the service station's sled (to which the servicing mechanism is fixed) with a plurality of correspondingly spaced posts.

The sled is generally held by a clamping member, which in turn is secured to the rack so that sled movement may be effected. To remove the sled from the clamping member, the printer's operator simply effects pinching action against a projection which extends angularly upward from the sled's base. The projection is pinched relative to a finger which extends upwardly from the clamp, such action, when the clamp and sled are combined, pushing the sled against a resilient member to cause upward biased sled release. A tight, no-slop, releasable coupling of the sled (and thus the servicing mechanism) to the clamp is thus provided.

These and other objects and advantages of the present invention will be understood more readily upon considering the drawings and the detailed description of the preferred embodiment which is set forth below.

Brief Description of the Drawings

Fig. 1 is an isometric view of a printer, such printer employing a printhead service station of the type described herein.

Fig. 2 is an enlarged isometric view of the improved service station, the service station being shown in isolation.

Fig. 3 shows the service station of Fig. 2 with several components removed better to expose the station's drive system.

Fig. 4 shows the drive system of Fig. 3 in isolation.

Figs. 5A and 5B illustrate operation of the drive system shown in Fig. 3, such view having been simplified so as to expose mechanism by which the drive system is stalled.

Figs. 6A through 6D show a sled/clamp combination which form a part of the service station of Fig. 2, disassociation of the sled and clamp being illustrated.

Fig. 7 shows the improved service station wherein the station's sled has been registered in the printer's printhead carriage.

Detailed Description and Best Mode for Carrying Out the Invention

Beginning with a general overview of the invention, and referring initially to Fig. 1, attention is drawn to the fact that the invented method and apparatus are suitable for use in an ink-jet printer 10 of somewhat conventional design. It is to be appreciated, however, that such method and apparatus may similarly be utilized in other style printers such as driven-pen printers, dot-matrix printers, or other somewhat dissimilar devices. Despite its adaptability, however, the method and apparatus are described herein specifically in the context of a ink-jet printer, a printer in which they have proven particularly useful.

As shown, printer 10 includes a chassis 12, such chassis defining a reference structure relative to which various instrumentality is moved as will be further described below. The depicted printer also includes (as is exposed in simplified form by partial break-away of its chassis) a reciprocating carriage 14 which holds a pair of printheads 14a, 14b. In the embodiment shown in Fig. 1, printhead 14a is a monochrome (black) pen and printhead 14b is a tricolor (cyan, magenta, yellow) pen. During a print operation, the carriage reciprocates horizontally within the printer's chassis along a carriage shaft 15 with the printheads controllably depositing ink on print media which passes thereacross. Although printer 10 is fitted with a plural-printhead carriage in Fig. 1, those skilled in the art will recognize that the printer may be modified by a relatively simple operation to employ a single-printhead carriage. In either case, the printhead(s) will require periodic servicing by mechanism such as that included in the improved service station which is shown in generally simplified form at 16.

In a conventional ink-jet printer such as printer 10, printheads are serviced through the operation of various servicing tasks such tasks generally being necessary to maintain printhead viability. One such servicing task relates to the periodic wiping of printheads, a task which is described generally in a corresponding U.S. patent application entitled "Synchronized Carriage and Wiper Motion Method and Apparatus for Ink-jet Printers" naming Gast et al. as inventors and which is commonly owned herewith. Another servicing task concerns printhead capping, an example of such operation having been provided in U.S. Patent No. 5,027,134 entitled "Non-Clogging Cap and Service Station for Ink-jet Printers", which issued June 25, 1991 and which is also commonly owned herewith. Although both tasks are important, and both tasks are performed by the improved service station which is herein described, the capping task is chosen

5

EP 0 590 850 A2

6

as the primary example by which to explain the apparatus and methodology which form the present invention.

To effect servicing of the printer's printhead, it is desired to employ a newly developed printhead-servicing method which enables the printer economically to execute tasks such as those referenced above. Such method, it will be appreciated, is most useful in effecting proper printhead capping, particularly where capping is to be effected in a printer which may be modified to employ either a single- or a plural-printhead carriage. Different carriage configurations have in the past necessitated correspondingly different cap configurations and thus have made printhead capping an unnecessarily complex task. Printhead capping, however, may be simplified in view of the fact that only three carriage configurations are commonly used. Such configurations accommodate the use of: (1) a single monochrome printhead; (2) a single tricolor printhead; or (3) both a monochrome printhead and a tri-color printhead. Printheads employed in any of these configurations may be capped using the same service station arrangement (described further below) by exercising control over the carriage when the capping task is to be executed. Similarly, printhead wiping may controllably be effected by synchronous action of the carriage with the wipers without altering service station design or configuration.

Consequently, printhead service is accomplished in printer 10 using a method which begins with identifying the desired servicing task (e.g. capping both monochrome and tri-color printheads). Once the task is identified, a determination is made as to where the printhead(s) should be positioned during execution of the task and the carriage is moved so as to place the printhead(s) in such position(s). At this point, the task may be executed. In order to effect such operation automatically, carriage movement is preferably controlled by a processor such as a microprocessor of the type generally employed in printers of conventional design. The processor is generally supplied with information concerning the carriage configuration employed and with information which allows the processor to determine where the printhead should be positioned during the upcoming printhead-servicing task.

Turning now to a more specific description of the improved service station, and referring initially for this purpose to Fig. 2, the reader is provided with an isometric illustration of service station 16, such apparatus being shown independent of the printer. As indicated, the service station includes a framework 18, such framework effectively containing the service station so as to accommodate removal and replacement of the service station as a whole. The framework is configured for selected rigid securement to the printer's chassis, such framework including a pair of horizontally projecting hold-down mounts, one of

which is shown at 18a in Fig. 2.

The hold-down mounts, it will be understood, accommodate securement of the service station to boss 18 on the chassis' floor, such securement being achieved via suitable securement means such as screws (not shown). In the preferred embodiment, the hold-down mounts extend from adjacent opposite corners of the framework and the framework conforms to interior structure of the chassis so as to ensure a stable service-station/chassis combination. The framework is thus designed to provide a unique modular printer organization while, at the same time, maintaining rigid positional control of features critical to service station operation as will be understood upon further reading.

Referring still to Fig. 2, but focusing further on the features which effect servicing of printheads, it will be appreciated that the depicted service station includes a printhead-servicing sled 20 such sled being movable relative to the station's framework (and thus the printer's chassis) to effect servicing of the printer's printheads. The sled, it will be noted, carries various instrumentality, including printhead-servicing mechanism such as caps 22a, 22b and wipers 24a, 24b. Such servicing mechanism, as suggested by the relevant nomenclature, is useful in either wiping the printer's printheads (using wipers 24a, 24b), or capping the printer's printheads (using caps 22a, 22b), as generally described in the commonly owned invention disclosures referenced above. Those skilled in the art, for example, will understand that cap 22a is configured to effect capping of monochrome printhead 14b (see Fig. 1) and that cap 22b is configured to effect proper capping of a tri-color printhead 14a (see Fig. 1). The caps are mounted on the sled in positions which are known to the printer's processor so that proper carriage positioning may be achieved when any one of the above-identified carriage configurations is employed.

To save space within the printer's chassis, the improved service station provides for the servicing of printheads by vertically driven movement of the printhead-servicing sled. Such sled movement, it will be understood, results in movement of the printhead-servicing mechanism therewith. Servicing tasks are performed as the sled moves into one of several servicing elevations. Conventionally, sled movement into one of such servicing elevations effects capping or wiping of a printhead, but sled movement may also be effective to scrape the service station's wipers using a scraper such as that shown at 26 in Fig. 2. In the preferred embodiment, sled movement is processor-directed, allowing for precise adjustment of the sled.

Sled movement is effected by operation of a unique drive system 30, such system being partially obscured by motor housing structure 28a in Fig. 2, but shown in detail in Figs. 3 and 4. Although employed for illustrative purposes in this disclosure as being

employed in a printer service station, it is to be understood that such drive system is also suitable for use in various other devices which may or may not be related to printers. Such alternative drive system applications may, for example, include use in conveyors or any other devices where it is desirable to temporarily stall device operation. The drive system is operatively coupled with sled 20 via a clamping member 32, such member providing unique structure by which the sled is made readily removable. A more complete discussion of clamping member, however, has been delayed until such time as the description of the drive system has been completed.

Focusing attention now on the drive system, and referring specifically to Figs. 3 and 4, wherein the system is best shown, the reader will note that such system includes a drive train which selectively is driven by mechanism such as motor 28. As indicated, the drive train includes a rack 34 and a pinion gear 36 which together form a rack-and-pinion mechanism for conversion of rotational pinion movement into translational rack movement. The rack carries instrumentality such as the sled and the servicing mechanism to effect corresponding movement thereof. The drive train also includes a worm gear 38, such worm gear acting on the pinion gear to effect rotation thereof. All three drive train components are operatively driven by motor 28, but the worm gear is most directly connected to the motor via motor shaft 28b. As will be recognized by those skilled in the art, motor 28 may be of virtually any conventional design, but is preferably a stepper motor so that instrumentality such as the sled may readily be moved incrementally in the manner which will now be described.

Beginning with a review of the relationship between worm gear 38 and pinion gear 36, it will be noted that such worm gear includes a helical ridge which operates on the teeth of a central sprocket on pinion gear 36 to effect rotation thereof. A pair of smaller sprockets, which are linked to the central sprocket, correspondingly are turned, engaging the rack so as to effect translation thereof. In this manner, the worm gear is operatively coupled with the rack via the pinion gear. Upon worm gear rotation, the rack is translated, and upon worm gear lock the rack is locked. In the depicted embodiment, wherein motor 28 is coupled to the worm gear to effect drive thereof, the motor is similarly used to lock the rack in place by shutting the motor down. Where, as is preferred, the motor is a stepper motor, the track may be locked in place after each motor step. In the present service station embodiment, drive system locking is particularly beneficial when the printheads are capped so as to ensure maintenance of a proper seal.

As best shown in Fig. 3, but as also shown in Figs. 5A and 5B, rack 34 is captured by a pair of facing grooves in the service station framework so as to promote controlled reciprocal vertical translation of the

rack relative to the framework and thus relative to the printer's chassis. The rack rotatably grips clamping member 32, and the clamping member fixedly grips sled 20, so as to effect reciprocal transport of the sled by the rack. The clamp/sled combination follows a track which is defined by cammed engagement between the clamp and the framework, the clamp including a pair of pins 32a, which follow a pair of corresponding framework slots one of which is shown at 18b. Such slot, it will be appreciated, effects pivot of the clamp/sled combination during a first portion of the rack's reciprocation cycle (during pin movement horizontally through the slot) and effects linear, vertical translation during a second portion of the rack's reciprocation cycle (during movement vertically through the slot and beyond). Vertical clamp/sled movement is thus generally effected during printhead capping and wiping, and pivotal clamp/sled movement is generally effected during wiper scraping.

Another important feature of the drive system 30 concerns its ability to effect momentary stall of the rack without bringing about jamming of the worm or pinion gears. Such feature will be most readily understood upon reference to Figs. 5A and 5B. Rack stall is achieved by the provision of a movable stop such as that provided by end 40a of lever 40 in Fig. 5A. As indicated, when the lever is in a first position (shown in Fig. 5A), end 40a is in a corresponding first position so as to limit movement of the rack in a first direction P. Such limitation is effected by engagement between lever end 40a and rack 34 in a contact area 34a. End 40a, it will be understood, is put into such contact by its extension through an aperture 18c in framework 18. The rack, which is directed to move in a first vertical direction P, engages end 40a and thus restricts further movement of the rack in direction P. Because the rack is motor driven, and because the drive train between the rack and the motor includes interengaging mechanism such as gear teeth (and a helical ridge on the worm gear), torque will build up in the pinion gear and the worm gear so as to cause drive train jamming. At this point, the drive system may be unjammed, and the rack allowed to continue along its path in direction P by action of the lever so as to move end 40a out of the rack's path. Such second lever position, as best illustrated in Fig. 5B, allows passage of end 40a through aperture 18c into a second position which allows passage of the rack in the direction P and alleviates torque previously built up in the gear train.

In the preferred embodiment, the lever is biased to the first position, placing end 40a in a position such that the rack will contact the same so as to stall the rack in that position. Such bias, as best shown in Fig. 4, is caused by action of a torsion spring 42. To move the lever from its first position to its second position, a processor controlled actuator is employed. Such actuator may take varied forms, but is preferably the

printer's printhead carriage, such carriage 14 selectively engaging the lever as it passes into a printhead-servicing position as described above.

Upon system start up, the rack is raised to engage the stop, driving the worm gear in a wedged orientation relative to the pinion gear, resulting in torque build-up, and to eventual stall of the stepper motor. The stop is then removed by action of the actuator which engages the lever. This alleviates torque built up in the gears and allows the system to continue in the first direction toward the printheads. Upon stalling of the motor the processor may be directed to record the position of the rack, defining such position as the reference against which movements are thereafter measured.

As alluded to above, service station 16 is made further adaptable and more easily repairable by inclusion of a feature which allows for quick release of sled 20, and thus quick release of the printhead servicing mechanism secured thereto. Such feature is best shown in Figs. 6A-6D, which show the sled secured to clamp 32 in Figs. 6A and 6B, and then show release of the sled by a pinching action represented generally by force arrows F_a and F_b .

Upon reference to the drawings, it will be noted that the sled is generally held tightly by the clamping member using a pair of elongate, rigid clamp fingers 32b and a pair of elongate, resilient members 32f. The clamp fingers extend upwardly from the clamp's base in a forward region (from the user's perspective looking into the printer) and the resilient members extend upwardly from the clamp's base in a rearward region (again from the user's perspective looking into the printer). The fingers and resilient members are adequately spaced so as to accommodate secure capture of the sled therebetween. Specifically, the fingers and resilient members bear on the sled's base 20a, the resilient members urging the sled into engagement with the clamp fingers as shown. In order to ensure a properly oriented combination, the fingers are formed with a ridge 32d (best shown in Fig. 6D) which engages the sled's base. The clamp may also be formed with a protuberance 32c which is formed with an aperture 32e through which a lateral hinge member 20b extends.

The sled, which is specially designed to allow ready gripping and quick removal thereof, includes a series of elongate projections 20c which extend angularly upwardly from the sled's body. These projections, it will be appreciated, are arranged in pairs with the projections of each such pair extending from adjacent opposite sides of a corresponding finger when the sled and clamp are combined. The clamp fingers are provided with comfort-enhancing features such as surfaces which are at an angle similar to that of the sled's projections so as to promote easy sled removal as will now be described.

To remove the sled from the clamp, the printer's

operator simply pinches the sled projections toward the corresponding clamp finger as indicated by force arrows F_a and F_b in Fig. 6C. The sled moves back against the resilient members 32e, deflecting them rearwardly. Ridge 32d is thus removed from engagement with the sled body and the sled is allowed to pivot out of the clamp about hinge member 20b as shown in Fig. 6D. Because of the angulation of the sled projections, the above-described pinching action effects generally biased pivot about the sled's rear edge. The projections, in such an arrangement may be used as handle or grip means by which the sled is held, a feature particularly beneficial when replacing sleds used in ink-jet printers inasmuch as their bases may have ink on them. This arrangement also serves to take the relatively fragile resilient members away from the operator to protect them from inadvertent harm. A tight, no-slop, releasable coupling of the sled (and thus the servicing mechanism) to the clamp is thus provided.

Another unique feature of the improved service station disclosed herein relates to its printhead registration system. Such system, it will be appreciated is particularly useful in the capping of printheads, an operation which requires a precise and stable relationship between the printheads and the printhead caps which are mounted on the sled. The registration system employed is illustrated in Fig. 7, wherein the service station's sled 20 is registered in printhead carriage 14 (which rigidly holds the printheads as described above). Such registration is selectively effected upon vertical movement of the sled into a defined engagement with the carriage as when such carriage is in a servicing position for printhead capping.

In order to equip the printer with the ability to effect proper registration, the carriage is defined so as to have a plurality of spaced detents 44a-44d, each such detent being positioned so that it will be engaged by a corresponding sled post 46a-46d upon movement of the sled vertically into engagement therewith as described above. As indicated, vertical movement of the sled brings about combination of the posts and detents so as to effect restriction of relative rotation or translation between the two components about mutually-perpendicular X, Y, and Z axes. Although four posts are used, those skilled in the art will recognize that the desired registration may be accomplished using only three such posts.

In the embodiment shown, post 46a, by its engagement with detent 44a effects restriction of relative sled/carriage movement along the X axis. Engagement of post 46b with detent 44b effects a limit of continued vertical movement along the Z axis in the direction of relative approach. Posts 46c and 46d restrict movement along the Y axis and aid in restricting movement in the Z direction just described. All four of the posts cooperate to restrict rotation about each of the X, Y and Z axes by virtue of their spaced ori-

11

EP 0 590 850 A2

12

entation relative one another.

Industrial Applicability

It should thus be apparent that the invented methodology and apparatus solves the various problems related to the alignment, carriage and replacement of instrumentality, particularly with respect to mechanism used in the servicing of printheads. The solutions are suitable for use in a broad array of devices including various printers inasmuch as it is embodied in a modular service station arrangement which mounts servicing mechanism on a removable sled. To adapt the station for use on another printer or to repair or replace damaged or worn servicing mechanism, the user need only remove one sled and replace it with another sled which carries the desired mechanism. The drive system, which allows for improved carrying and alignment operations, is of the broadest industrial applicability, being suitable for use in virtually any device where it is desirable to temporarily stall device operation. Herein, however, such system forms a part of the improved service station and is readily removable therewith.

While the present invention has been disclosed with reference to the foregoing operation principles and the preferred embodiment shown in the drawings and described above, it will be apparent to those skilled in the art that changes in form and detail may be made therein without departing from the spirit and scope of the invention as it is defined by the appended claims.

Claims

1. In a printer (10) having a chassis (12) and a service station (16) for use in servicing the printer's printhead (14a, 14b), the improvement comprising: a framework (18) which forms a part of the service station (16) and generally contains the same, said framework (18) being configured for selected removable securement to the printer's chassis (12) such that removal of said framework (18) from the chassis (12) effects removal of the service station (16) therewith.
2. The printer (10) of claim 1, wherein the improvement further comprises a sled (20) which forms a part of the service station (16), said sled (20) selectively being removable therefrom.
3. In a printer (10) having a chassis (12) and a service station (16) for use in servicing the printer's printhead (14a, 14b), the improvement comprising: a printhead-servicing sled (20) which forms a part of the service station (16), said sled (20) being mounted for vertical movement into a ser-

ving elevation; and a drive system (30) operatively coupled with said sled (20) for driving the same vertically into said servicing elevation.

4. The printer (10) of claim 3, wherein the improvement further comprises a printhead cap (22a, 22b) operatively mounted on said sled (20), movement of said sled (20) into said servicing elevation being effective to cap the printhead (14a, 14b).
5. The printer (10) of claim 3, wherein the improvement further comprises a printhead wiper (24a, 24b) operatively mounted on said sled (20), movement of said sled (20) into said servicing elevation, along with synchronous movement of the printhead (14a, 14b), being effective to wipe the printhead (14a, 14b).
6. The service station (16) of claim 3, wherein the said drive system (30) includes a pinion gear (36) which drives a sled-carrying rack (34), said pinion gear (36) being operatively coupled with a worm gear (38) configurable selectively to lock said rack (34) in place.
7. A drive system (30) mounted relative to a reference structure for use in effecting controlled movement of instrumentality relative to the reference structure, the drive system (30) comprising: a rack-and-pinion mechanism including a instrumentality-carrying rack (34) and a rotating pinion gear (36), said pinion gear (36) being mounted to effect translation of said rack (34) relative to the reference structure; and a worm gear (38) operatively coupled with said rack (34) via said pinion gear (36) selectively to lock said rack (34) in place.
8. The system (30) of claim 7 further comprising a motor (28) coupled with said worm gear (38) selectively to drive the same.
9. The system (30) of claim 8, wherein said motor (28) is a stepper motor (28), said rack (34) being lockable after each motor step.
10. A drive system (30) mounted relative to a reference structure for use in effecting movement of instrumentality relative to the reference structure, said system (30) comprising: a rack (34) mounted relative to the reference structure for movement in a first direction; a driven pinion gear (36) operatively coupled with said rack (34) to effect movement thereof in said first direction; and a stop (40a) controllably movable from a first position wherein said stop (40a) limits movement of said rack (34) in said first direction to a second

13

EP 0 590 850 A2

14

- position wherein said stop (40a) allows further movement of said rack (34) in said first direction.
11. The system (30) of claim 10, wherein said stop (40a), when in said first position, limits movement of said rack (34) by passage of the same into operative engagement with said stop (40a). 5
 12. The system (30) of claim 10, wherein said stop (40a) is yieldably biased toward said first position. 10
 13. The system (30) of claim 10 further comprising an actuator configured selectively to move said stop (40a) from said first position to said second position. 15
 14. The system (30) of claim 13, wherein said actuator is processor controlled. 20
 15. The system (30) of claim 13, wherein said actuator selectively engages said stop (40a) to effect movement thereof to said second position.
 16. The system (30) of claim 10 further comprising a worm gear (38) operatively coupled with said pinion gear (36) for driving the same. 25
 17. The system (30) of claim 16, wherein said worm gear (38) is motor-driven. 30
 18. The system (30) of claim 16, wherein said worm gear (38) is driven into wedged orientation when said stop (40a) is in said first position, said worm gear (38) being released upon movement of said stop (40a) into said second position. 35
 19. The system (30) of claim 16, wherein said worm gear (38) is processor-controlled. 40
 20. The system (30) of claim 16, wherein said worm gear (38) is effective selectively to lock said rack (34) in place.
 21. A printhead-servicing method for use in a printer (10) having a printhead (14a, 14b) which is selectively horizontally movable into various printhead-servicing positions such that corresponding servicing tasks may be executed by servicing mechanism mounted on a printhead-servicing sled (20), the method comprising: identifying the desired servicing task; identifying the desired printhead-servicing position of the printhead (14a, 14b) during execution of the identified servicing task; moving the printhead (14a, 14b) horizontally to the identified printhead-servicing position; and executing the identified servicing task. 45 50 55
 22. The method of claim 21, wherein said moving of the printhead (14a, 14b) is processor controlled.
 23. The method of claim 21, wherein the servicing mechanism is mounted on a vertically movable printhead-servicing sled (20), said executing of the servicing task being effected by moving the sled (20) vertically.
 24. The method of claim 23, wherein said moving of the sled (20) vertically effects printhead capping.
 25. The method of claim 23, wherein said moving of the sled (20) vertically is accompanied by synchronized moving of the printhead (14a, 14b) horizontally to effect printhead wiping.
 26. In a printer (10) having a service station (16) for use in servicing the printer's printhead (14a, 14b), a printhead registration system which comprises: a horizontally movable carriage (14) which carries the printer's printhead (14a, 14b), said carriage (14) defining a plurality of spaced detents (44a-44d) therein; and a vertically movable sled (20) which forms a part of the service station (16), said sled (20) including a plurality of spaced posts (46a-46d) configured for combination with said carriage detents (44a-44d), said combination being effective to restrict relative rotation of said carriage (14) and said sled (20) about a vertical axis.
 27. The system (30) of claim 26, wherein said carriage (14) includes at least three detents (44a-44d) and said sled (20) includes a corresponding number of posts (46a-46d), the combination of said posts (46a-46d) and detents (44a-44d) being effective to further restrict relative rotation of said carriage (14) and said sled (20) about perpendicular horizontal axes, effectively restricting all relative rotation.
 28. The system (30) of claim 26, wherein at least one of said posts (46a-46d) engages a corresponding one of said detents (44a-44d) to effect a limit to relative translation between said carriage (14) and said sled (20) along a horizontal axis perpendicular to a horizontal axis of carriage travel.
 29. The system (30) of claim 26, wherein at least said posts (46a-46d) engages a corresponding one of said detents (44a-44d) to effect a limit to relative translation between said carriage (14) and said sled (20) along a horizontal axis of carriage (14) travel.
 30. The system (30) of claim 26, wherein at least one of said posts (46a-46d) engages a corresponding

16

one of said detents (44a-44d) to effect a limit to relative translation between said carriage (14) and said sled (20) in a first direction along a vertical axis.

5

31. In a printer (10) having a service station (16) for use in servicing the printer's printhead (14a, 14b), the improvement comprising: a printhead-servicing sled (20) which forms a part of the service station (16), said sled (20) including a base (20a) and a projection (20c) which extends angularly upward from said base (20a); and a clamping member (32) configured selectively to capture said sled (20), said clamping member (32) including an upwardly extending finger (32b) and an upwardly extending resilient member (32f) spaced from said finger (32b) to allow removable capture of said sled (20) therebetween, said finger (32b) being positioned, upon sled capture, to extend adjacent said projection (20c) to accommodate deflection of said resilient member (32f) by pinching action against said projection (20c) and said finger (32b) so as to release said sled (20) from capture.

10

15

20

25

32. The service station (16) of claim 31, wherein said finger (32b) includes a ridge (32d) which engages said base (20a) upon sled capture, deflection of said resilient member (32f) effecting disengagement of said base (20a) relative to said ridge (32d) and allowing sled release.

30

33. The service station (16) of claim 31, wherein said projection (20c) accommodates ready grip thereof.
